

FitBuddy Project

Topic 7 – Environment Setup

A Python virtual environment keeps project packages separate from other Python projects.

Key Points

- Create an environment with: `python -m venv venv`
- Activate the environment before installing dependencies.
- Install dependencies using: `pip install -r requirements.txt`
- Use environment variables for sensitive configuration such as the Gemini API key.
- A `.env` file can be loaded using `python-dotenv` during local development.

Project relevance: This topic is one of the required pre-requisites for developing and running the FitBuddy application.
